

**ECEN 4013**  
*Design of Engineering Systems*

# **Agenda**

**Electrical Safety**  
**Project 1 Introduction**  
**Project 1 Team Assignments**

# Electrical Safety Review

This electrical safety review is prepared for engineering students in ECEN 4013, ECEN 4024, and Interdisciplinary projects.

A quiz on this material is on Canvas. ECE students must pass with a score of 100% in a maximum of three attempts.

# Electrical Safety Review

This review will cover only  $120V_{\text{rms}}$  domestic wall power. Any other project power sources may require specialized safety training.

$120V_{\text{rms}}$  wall outlets in ENDEAVOR and other campus buildings are fundamentally the same as a domestic power arrangement.

# 15 Amp Duplex Receptacle

# 20 Amp Duplex Receptacle

# Receptacle Wiring Nomenclature

# Receptacle Face

# Receptacle Back

# Receptacle Neutral Side

# Receptacle Hot Side

# Receptacle Ground

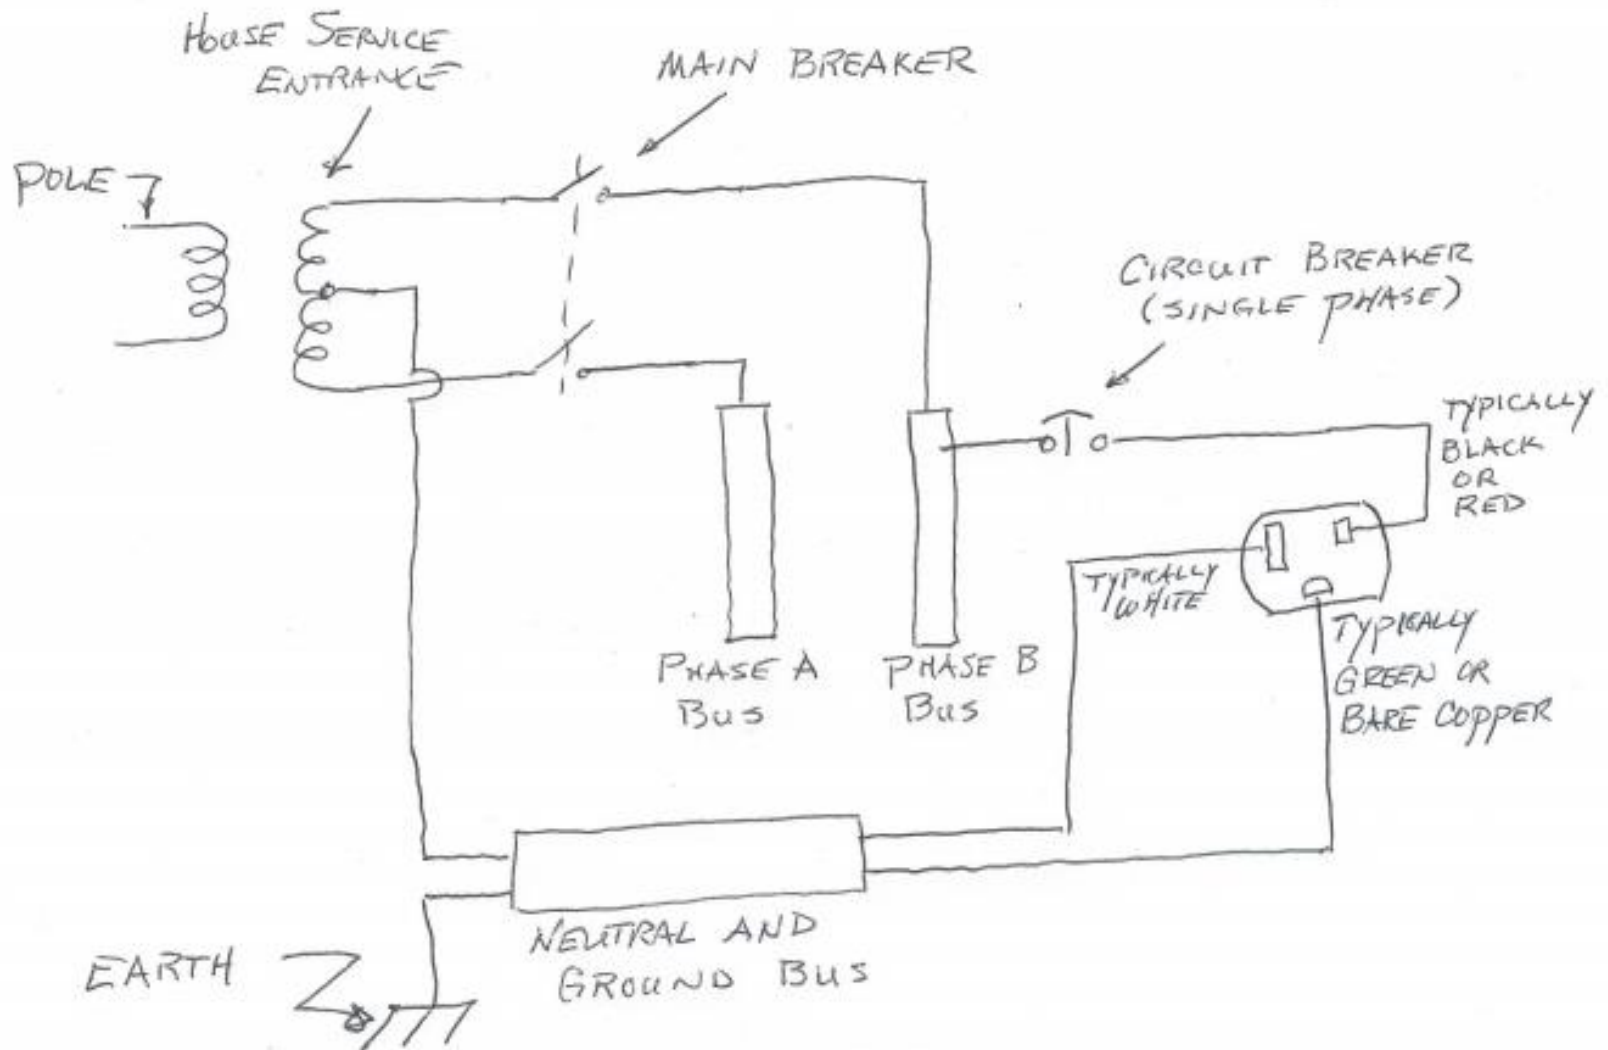

# Typical Domestic Power Panel

Typical US domestic color conventions  
(receptacle and plug wiring):

Hot	Black or Red
Neutral	White
Ground	Green or bare copper; possibly green with yellow stripe

European and some purchased cord set  
color conventions are different.

# Typical Domestic Power Panel

# Using AC power in the lab

Do not work on energized equipment – disconnect from the outlet.

Open and lock out the breaker when possible.

After working on equipment, confirm all voltages using a voltmeter.

# Using AC power in the lab

Confirm correct power switch operation using a voltmeter.

Remove rings and other jewelry in the laboratory – they are conductors!

Keep one hand in a pocket when making AC voltage measurements.

# Using AC power in the lab

Breakers, switches, and equipment can be wired incorrectly – take nothing for granted. Check it yourself.

Ask for help – take no risks.

No horseplay or practical jokes – lab work is serious business.

# How is single-phase power specified?

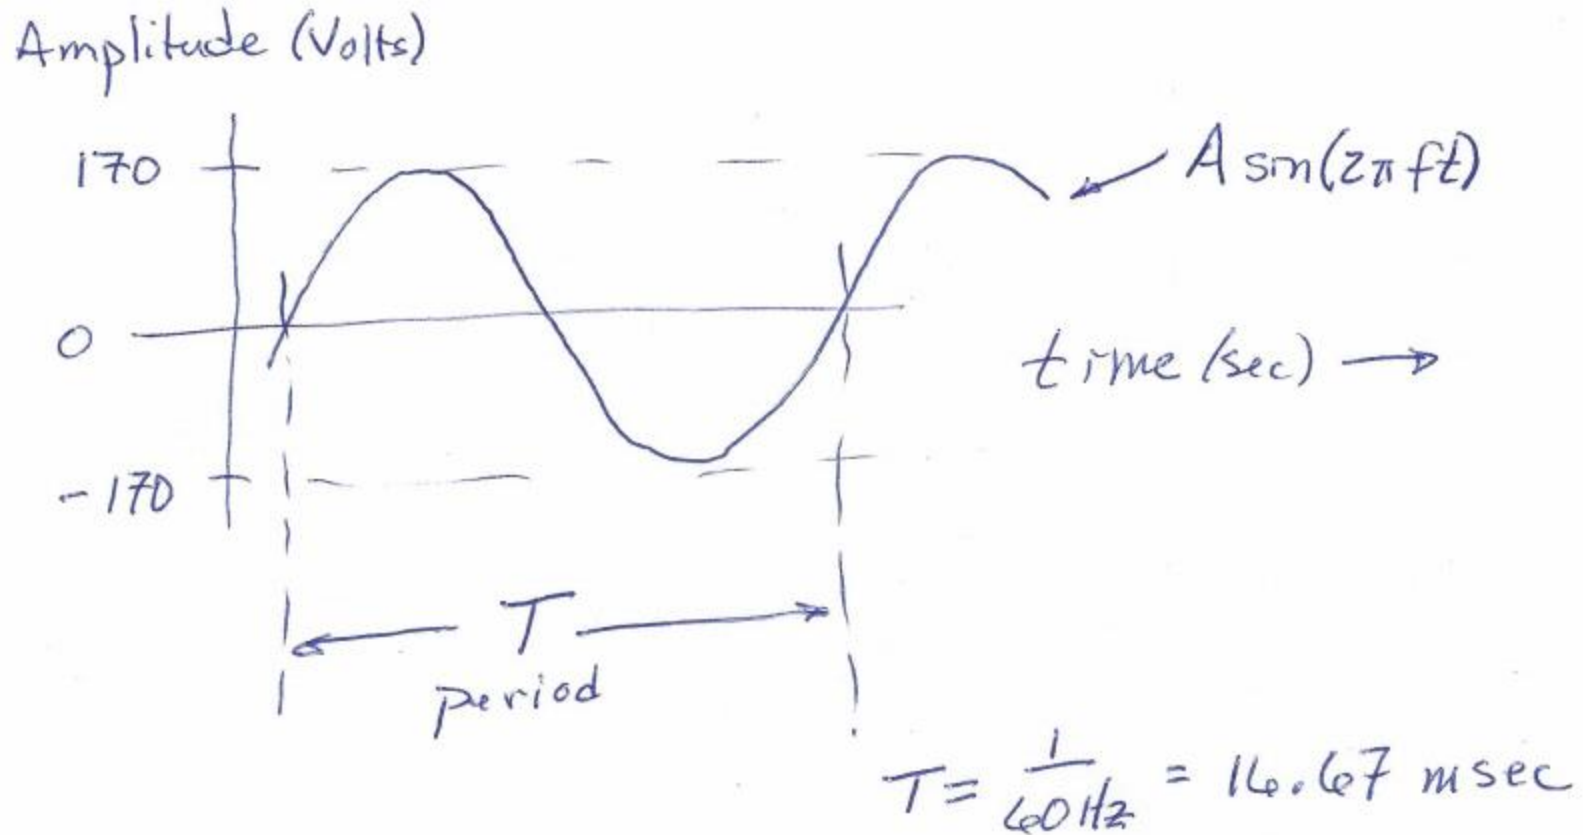

There are three different ways:

Amplitude of a sine wave (V)

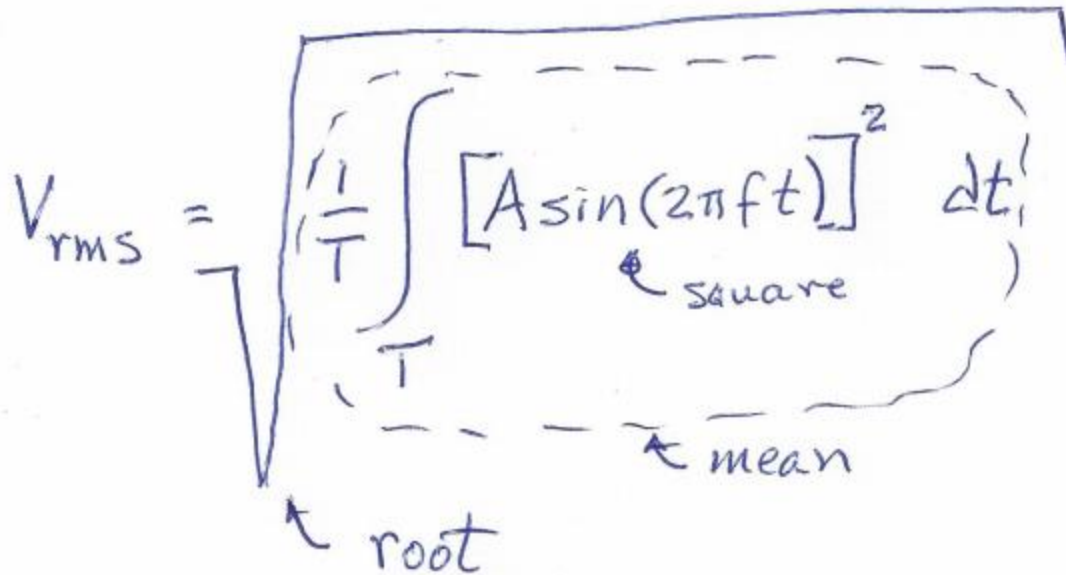

Peak-to-peak voltage ( $V_{p-p}$ )

Rms voltage ( $V_{rms}$ )

# US domestic single-phase power

# Root-mean-square (*rms*) calculation

A handwritten diagram illustrating the formula for Root-Mean-Square (RMS) calculation. The formula is written as  $V_{rms} = \sqrt{\left( \frac{1}{T} \int [A \sin(2\pi f t)]^2 dt \right)}$ . The diagram includes several annotations: a bracket under the square root is labeled "root"; a bracket under the integral term  $\left( \frac{1}{T} \int [A \sin(2\pi f t)]^2 dt \right)$  is labeled "mean"; and an arrow points to the squared term  $[A \sin(2\pi f t)]^2$  with the label "square".

rms = root mean square

# Single-phase AC voltage amplitude

Domestic distribution line voltage is nominally 120 V<sub>ac</sub>. 120 V<sub>ac</sub> is really 120 V<sub>rms</sub>: the root mean square voltage of an assumed undistorted sinusoid.

Nominal means “in name only.” In reality, the common AC power line can be anywhere between 105 V<sub>ac</sub> to 125 V<sub>ac</sub>.

# Single phase AC voltage amplitude

A single-phase sinusoid is commonly specified in three different ways.

$$\begin{aligned} 120 \text{ V}_{\text{rms}} &= 170 \sin(2\pi f t) \text{ Volts} \\ &= 340 \text{ V}_{\text{p-p}} \end{aligned}$$

You must understand these relationships when selecting component voltage ratings.

# Ground Fault Circuit Interrupter

- In normal operation, the hot and neutral conductors to a load must carry the same current.
- If hot and neutral currents aren't the same, the difference current has to be going somewhere. This is called a ground fault. The missing current is assumed to be going to ground - somewhere.

# Ground Fault Circuit Interrupter

- The National Electric Code mandates use of GFCIs in specific locations, particularly within six feet of water – typically, kitchens and bathrooms.
- What current difference is required to trip?
  - Class A: 5 mA (common use)
  - Class B: 20 mA (pools)

# Project 1

## 4-bit Successive Approximation A to D Converter

Major elements:

- Sample/hold amplifier (S/H)
- D/A converter
- Comparator (Schmitt trigger recommended)
- Storage register
- Clock
- Control and sequencing logic

# Project 1

# Initial Specifications: Project #1

Create a 4-bit unipolar input SAR A/D converter which will

- (1) Initiate a conversion sequence on command
- (2) Present a digital parallel 4-bit conversion result (nibble) when data ready.

# Initial Specifications: Project #1

3. Have an input range of 0-5 VDC.
4. Have a data conversion of at least 100 samples/second (sps). Conversion rate in excess of 1 ksps is desired.
5. No missing codes.

# Initial Specifications: Project #1

- (6) Have a unipolar power source or bipolar supply connections from bench power supply.
- (7) Have an adequate associated test plan in which all tests pass.

Your design must not use any modern processors with the following exceptions:

- Act as control for your AD converter.
- to transfer data and display the result.

Anything that is part of the 4000-series CMOS family or equivalent is fair game. You have a budget of \$100 for parts that cannot be found in the part store.

## A few notes on A/D converters

- Convert an analog voltage into a digital representation
  - e.g., 2.45v  0110
  - This conversion is dependent on the range of voltages to be converted and the number of bits used to represent the voltage

# Notes on A/D Converters

Resolution: the smallest possible change that can be identified (resolved). Also called Least Significant Bit (LSB).

The term “LSB” or “counts” is used in several different ways. For example, a signal may have “five counts of noise.” This means the observed noise is equivalent to five times the value of the LSB.

# Notes on A/D Converters

Bits of resolution	Number distinct values	Theoretical resolution
4	16	6.25%
8	256	0.39% = 3906 ppm
10	1024	977 ppm
12	4096	244 ppm
14	16384	61 ppm
16	65536	15 ppm
20	1048576	1 ppm

# Notes on A/D Converters

Resolution and reference voltage are related, because sampled signal values are interpreted as a binary fraction of the reference voltage.

If  $V_{\text{ref}} = 5.00 \text{ V}_{\text{DC}}$  and we are doing an 8-bit conversion,

$$\text{Resolution} = 5\text{V}/(256 \text{ values}) = 19.5 \text{ mV/value}$$

# Notes on A/D Converters

If  $V_{\text{ref}} = 4.096 V_{\text{DC}}$  and we are doing a 12-bit conversion,

$$\text{Resolution} = 4.096\text{V} / (4096 \text{ values}) = 1\text{mV/value}$$

The digitized signal value is equal to the number of counts (binary value) multiplied by the resolution. Any error from the original signal is called digitization noise.

# Your Homework Assignments due before next class

Take the electrical safety quiz (on Canvas).

Upload survey with your picture so that I can get to know you.

Download MultiSim and KiCad and run the tutorials. Instructions are found on Canvas (use new instructions I sent for MultiSim found in Canvas Announcements) .

Create a user for icescrum on <http://daleksec.es-private.okstate.edu:8080/icescrum/> (do not use icescrum.com, we have our own private server so that we can have teams larger than 2)

Get with your groups and assign roles

- POC - You will be in charge of contacting your TAs when you have questions and need to order parts
- Scrum Master – We will go over creating a project in iceScrum on Monday
